SCIENTIFIC REPORTS

OPEN

Genomic and metagenomic signatures of giant viruses are ubiquitous in water samples from sewage, inland lake, waste water treatment plant, and municipal water supply in Mumbai, India

Anirvan Chatterjee¹, Thomas Sicheritz-Pontén², Rajesh Yadav³ & Kiran Kondabagi¹

We report the detection of genomic signatures of giant viruses (GVs) in the metagenomes of three environment samples from Mumbai, India, namely, a pre-filter of a household water purifier, a sludge sample from wastewater treatment plant (WWTP), and a drying bed sample of the same WWTP. The *de novo* assembled contigs of each sample yielded 700 to 2000 maximum unique matches with the GV genomic database. In all three samples, the maximum number of reads aligned to Pandoraviridae, followed by Phycodnaviridae, Mimiviridae, Iridoviridae, and other Megaviruses. We also isolated GV from every environmental sample ($n=20$) we tested using co-culture of the sample with *Acanthamoeba castellanii*. From this, four randomly selected GV were subjected to the genomic characterization that showed remarkable cladistic homology with the three GV families viz., Mimiviridae (*Mimivirus Bombay* [MVB]), Megaviruses (*Powai lake megavirus* [PLMV] and *Bandra megavirus* [BAV]), and Marselleviridae (*Kurlavirus* [KV]). All 4 isolates exhibited remarkable genomic identity with respective GV families. Functionally, the genomes were indistinguishable from other previously reported GV families, encoding nearly all COGs across extant family members. Further, the uncanny genomic homogeneity exhibited by individual GV families across distant geographies indicate their yet to be ascertained ecological significance.

The discovery of *Acanthamoeba polyphaga mimivirus* (APMV)^{1,2} galvanized the search for other giant viruses (GVs). Subsequently, GV have been isolated from diverse environmental niches, including cooling towers, sewage, fresh water, and coastal water³. In fact, nucleocytoplasmic large DNA viruses (NCLDV) in the photic layer of oceans were thought to outnumber the eukaryotic organisms⁴. Metagenomic identification of *Klosneuvirus*, a new GV family, from wastewater treatment plant (WWTP) and their detection in the existing environmental metagenomes indicated their previously undetected presence⁵. Despite the discovery of several GV families, very little is known about their natural hosts, their role in the ecology, and biogeochemical pathways. While the Phycodnaviridae members are believed to control the planktonic communities⁶, the role of other GV in their environment is largely unknown.

The current classification of NCLDV consists of six closely related families of amoebal megaviruses, namely, Mimiviridae, Marselleviridae, Pandoraviridae, Pithoviridae, Faustoviridae, and Molliviridae⁷. While the evolutionary genealogy of NCLDV remains highly debated^{8–11}, the comparative genomics of several new amoebal NCLDV genomes from diverse geographies have augmented their accurate familial classification^{12–17}. Both genome expansion^{18,19} and reduction²⁰ models have been explored for explaining the evolution of the large

Global monitoring of antimicrobial resistance based on metagenomics analyses of urban sewage

Rene S. Hendriksen¹, Patrick Munk², Patrick Njage¹, Bram van Bunnik³, Luke McNally³, Oksana Lukjancenko¹, Timo Röder¹, David Nieuwenhuijsen⁴, Susanne Karlsmose Pedersen¹, Jette Kjeldgaard¹, Rolf S. Kaas¹, Philip Thomas Lanken Conradsen Clausen¹, Josef Korbinian Vogt¹, Pimlapas Leekitcharoenphon¹, Milou G.M. van de Schans⁵, Tina Zuidema⁵, Ana Maria de Roda Husman⁶, Simon Rasmussen⁷, Bent Petersen⁷, The Global Sewage Surveillance project consortium⁸, Clara Amid⁹, Guy Cochrane⁸, Thomas Sicheritz-Pontén⁹, Heike Schmitt⁶, Jorge Raul Matheu Alvarez¹⁰, Awa Aidara-Kane¹⁰, Sünje J. Pamp¹, Ole Lund², Tine Hald¹, Mark Woolhouse², Marion P. Koopmans⁴, Håkan Vigre¹, Thomas Nordahl Petersen¹ & Frank M. Aarestrup¹

Antimicrobial resistance (AMR) is a serious threat to global public health, but obtaining representative data on AMR for healthy human populations is difficult. Here, we use metagenomic analysis of untreated sewage to characterize the bacterial resistome from 79 sites in 60 countries. We find systematic differences in abundance and diversity of AMR genes between Europe/North-America/Oceania and Africa/Asia/South-America. Antimicrobial use data and bacterial taxonomy only explains a minor part of the AMR variation that we observe. We find no evidence for cross-selection between antimicrobial classes, or for effect of air travel between sites. However, AMR gene abundance strongly correlates with socio-economic, health and environmental factors, which we use to predict AMR gene abundances in all countries in the world. Our findings suggest that global AMR gene diversity and abundance vary by region, and that improving sanitation and health could potentially limit the global burden of AMR. We propose metagenomic analysis of sewage as an ethically acceptable and economically feasible approach for continuous global surveillance and prediction of AMR.

Hounmanou YM, Leekitcharoenphon P, Hendriksen RS, Dougnon TV, Mdegela RH, Olsen JE and Dalsgaard A (2019) Surveillance and Genomics of Toxigenic *Vibrio cholerae* O1 From Fish, Phytoplankton and Water in Lake Victoria, Tanzania.
Front. Microbiol. 10:901.
doi: 10.3389/fmicb.2019.00901

The occurrence of toxigenic *Vibrio cholerae* O1 during a non-outbreak period in Lake Victoria was studied and genetic characteristics for environmental persistence and relatedness to pandemic strains were assessed. We analyzed 360 samples of carps, phytoplankton and water collected in 2017 during dry and rainy seasons in the Tanzanian basin of Lake Victoria. Samples were tested using PCR (*ompW* and *ctxA*) with DNA extracted from bacterial isolates and samples enriched in alkaline peptone water. Isolates were screened with polyvalent antiserum O1 followed by antimicrobial susceptibility testing. Whole genome sequencing and bioinformatics tools were employed to investigate the genomic characteristics of the isolates. More *V. cholerae* positive samples were recovered by PCR when DNA was obtained from enriched samples than from isolates (69.0% vs. 21.3%, $p < 0.05$), irrespectively of season. We identified ten *V. cholerae* O1 among 22 *ctxA*-positive isolates. Further studies are needed to serotype the remaining *ctxA*-positive non-O1 strains. Sequenced strains belonged to El Tor atypical biotype of *V. cholerae* O1 of MLST ST69 harboring the seventh pandemic gene. Major virulence genes, *ctxA*, *ctxB*, *zot*, *ace*, *tcpA*, *hlyA*, *rtxA*, *ompU*, *toxR*, *T6SS*, *alsD*, *makA* and pathogenicity islands VP1-1, VP1-2, VSP-1, and VSP-2 were found in all strains. The strains contained *Vibrio* polysaccharide biosynthesis enzymes, the *mshA* gene and two-component response regulator proteins involved in stress response and autoinducers for quorum sensing and biofilm formation. They carried the SXT integrative conjugative element with phenotypic and genotypic resistance to aminoglycoside, sulfamethoxazole, trimethoprim, phenicol, and quinolones. Strains contained a multidrug efflux pump component and were resistant to toxic compounds with copper homeostasis and cobalt-zinc-cadmium resistance proteins. The environmental strains belonged to the third wave of the seventh pandemic and most are genetically closely related to recent outbreak strains from
